Clinical picture

Lab results and interpretation

Pre-investigations

Amino acid analysis

Organic acid analysis

Purines/pyrimidines analysis

Mucopolysaccharide analysis

Oligosaccharide analysis

Other analyses performed

Analytical Proficiency

2 points

Interpretation(diagnosis)

Advice for follow up investigations

2 points

# ERNDIM Proficiency Scheme: Errors

- Appropriate assay/method not used/available
- **Incorrect** analyte recognition
- **Incomplete** analyte recognition
- Correct analyte recognition BUT **incorrect** interpretation
- **Incorrect** confirmatory test

# ERNDIM Proficiency Scheme: Errors

- Appropriate assay/method not used/available  
e.g. Guanidinoacetate methyltransferase deficiency

## Sample F: GAMT deficiency

**Patient:** a 7-year old girl with developmental retardation, in particular speech delay. She has epilepsy, for which she is treated with valproic acid.

**Analytic:** elevated guanidinoacetic acid: 640 mmol/mol (ref. values <129)

Guanidino-acetic acid in plasma 27.2 umol/L (ref values 0.5-3.6),

**Interpretation:** guanidino-acetic acid methyltransferase (GAMT, EC 2.1.1.2) deficiency (OMIM 612736)

**Analytical performance:** Measurement of guanidinoacetic acid and creatine was critical for this sample. Those labs (**11 of 19**) that performed these assays found the relevant abnormality.

**Interpretative proficiency:** Interpretation is straightforward and was correct in all cases in which the relevant analysis was performed.

**Recommendations:** Measurements of GAA and creatine in plasma backed up by GAMT enzyme and / or mutation analysis (601240) was considered helpful.

	n	Points
<b>Guanidino-acetate methyltransferase deficiency (GAMT)</b>	11	2
<b>Glycinuria secondary to valproate medication.</b>	2	0
<b>No diagnosis obtained</b>	5	0
<b>biotinidase deficiency</b>	1	0

# ERNDIM Proficiency Scheme: Errors

## Incorrect analyte recognition

e.g. Arginino succinic aciduria

**Patient:** this sample came from a 20 year old male patient with ASAuria (OMIM 207900) who is under treatment with arginine. This sample was also distributed in 2009.

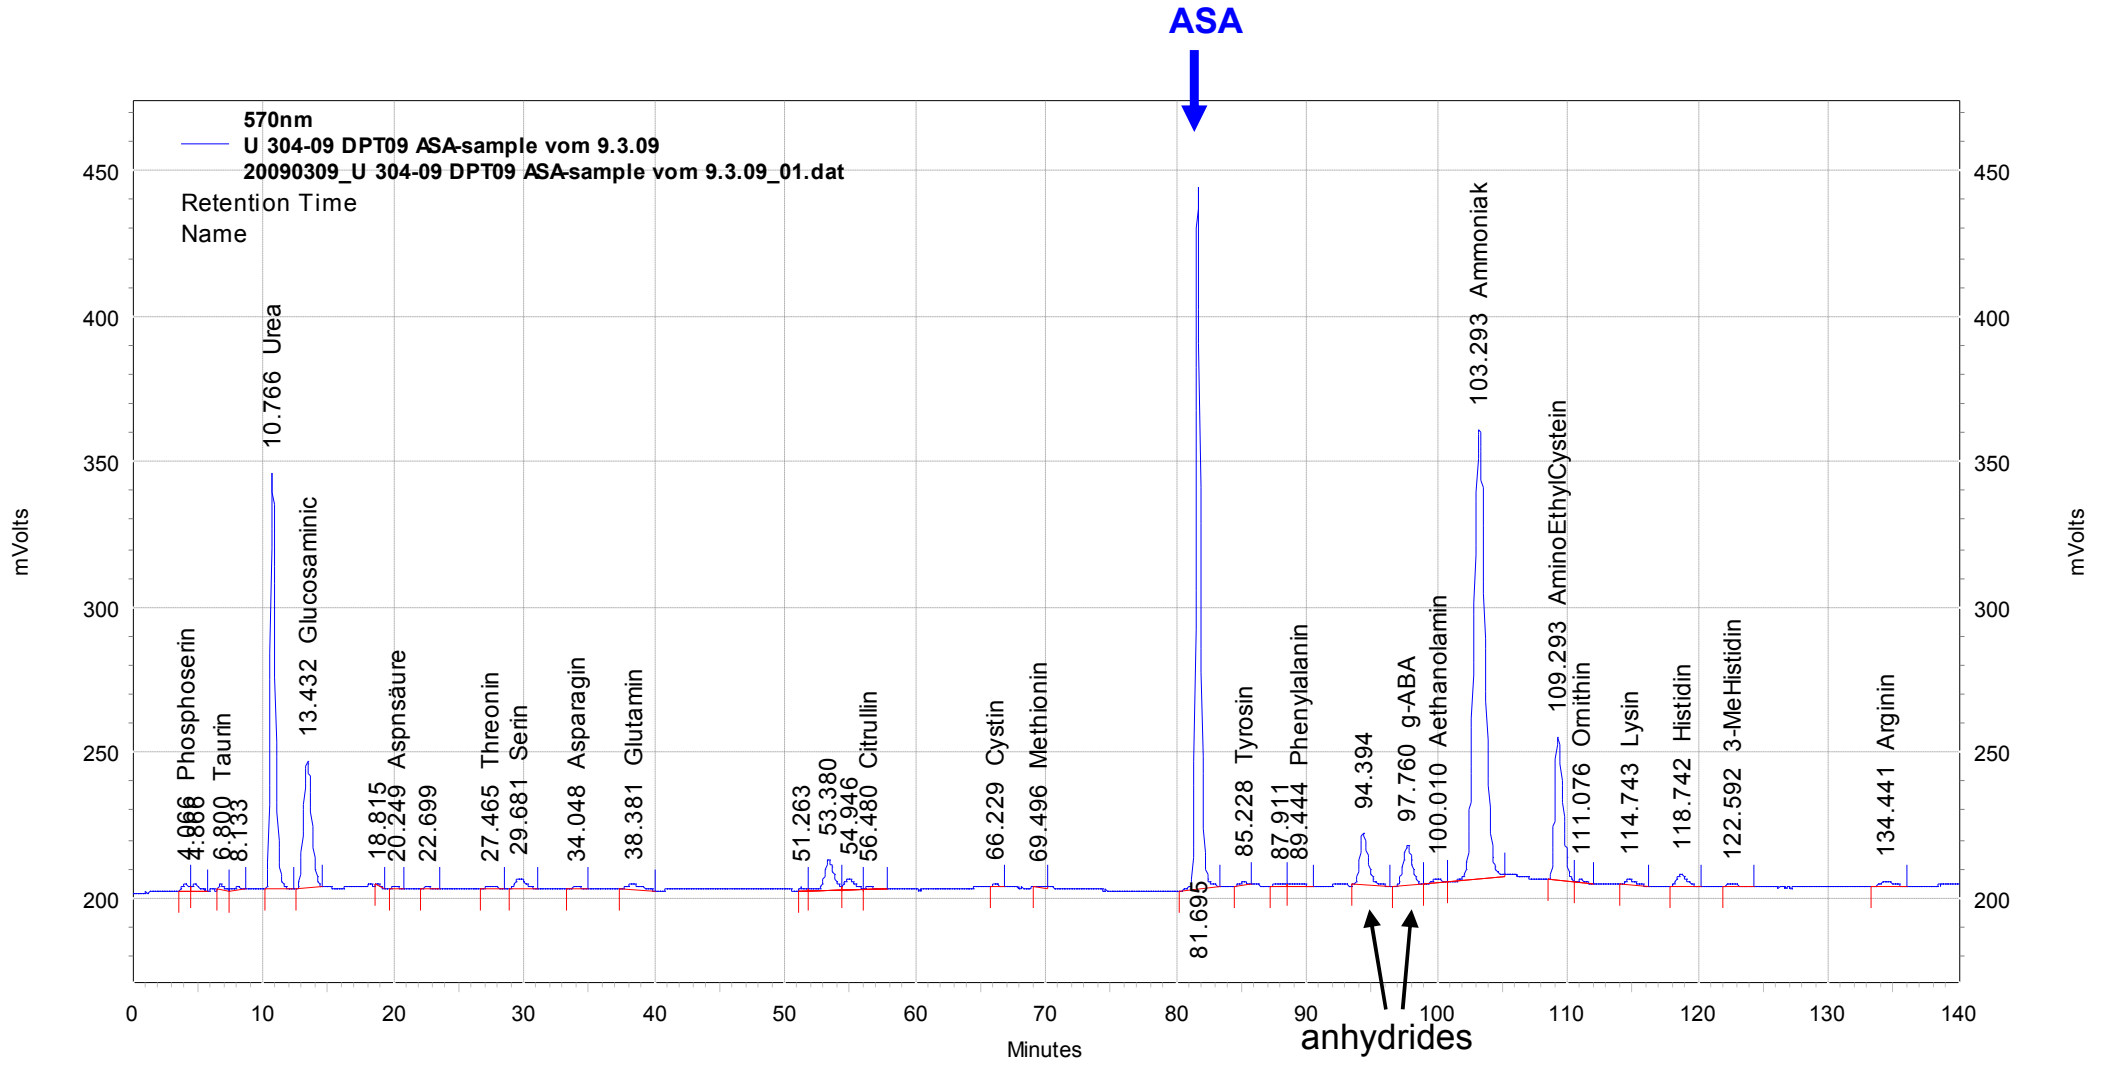

**Analytical performance:** Two points were given for identification of ASA and/or its anhydrides. **18 of 20** labs identified key metabolites pointing to the correct diagnosis.

**Interpretative proficiency:** The correct diagnosis was arginino-succinic aciduria due to ASA-lyase deficiency (EC 4.3..21). 18/20 labs made the correct diagnosis.

**Overall impression:** All labs should be able to identify arginino-succinic acid and its anhydrides, there appear to be some difficulties in identification on some amino acid analysers.

	n	Points
<b>Argininosuccinic aciduria due to argininosuccinate lyase deficiency)</b>	<b>18</b>	<b>2</b>
<b>Hyperprolinaemia</b>	<b>1</b>	<b>0</b>
<b>VinylGABA therapy</b>	<b>1</b>	<b>0</b>

# Amino acid analysis by Ion exchange chromatography

# ERNDIM Proficiency Scheme: Errors

## Incomplete analyte recognition

e.g. Combined malonic and methylmalonic aciduria due to mutations in the ACSF3 gene.

**Patient:** At 20 y. of age investigated for bowel problems and serum methylmalonate was elevated. Urinary organic acid analysis showed methylmalonate, 73 mmol/mol creat. and malonate, 13 mmol/mol creat. Two mutations in the ACSF3 gene were identified.

**Analytical performance:** The finding of increased methylmalonic acid was scored with one point (20 labs) and increased malonic acid with one point (10 labs).

**Interpretative proficiency:** The correct diagnosis was combined malonic acid and methylmalonic aciduria scoring two points (9 labs). Other diagnoses based on finding methylmalonic acid alone were scored with 0 points.

**Overall impression:** This was a fairly difficult sample but it was clearly possible to detect increased malonic acid as reported by ten labs pointing to the correct diagnosis.

<b>Combined malonic and methylmalonic aciduria</b>	<b>9</b>	<b>2</b>
<b>Malonic aciduria</b>	<b>1</b>	<b>0</b>
<b>Mild MMA/B12 deficiency</b>	<b>10</b>	<b>0</b>

# ERNDIM Proficiency Scheme: Errors

Correct analyte recognition BUT incorrect interpretation  
e.g. 4-Hydroxybutyric aciduria

**Patient:** The urine was obtained from a 7 months old patient with confirmed 4-hydroxybutyric aciduria (succinate-semialdehyde dehydrogenase deficiency, EC 1.2.1.16).

**Analytical performance:** The finding of 4-hydroxybutyric acid with or without other key metabolites such as 3,4-dihydroxybutyric acid was considered to be correct. Overall performance was high at 95%.

**Interpretative proficiency:** The correct diagnosis was considered to be 4-hydroxybutyric aciduria due to SSADH deficiency (OMIM 271980). Proficiency for interpretation for this sample was also good at 90%.

## Lab X

**Analytical:** 4-Hydroxybutyric acid 71 mmol/mol Creat. (Ref <10)      2 points

**Interpretation:** Mucopolysaccharidosis (tentative)  
Clinical suggestion      0 point

# Sample D: Total Ion Chromatogram

# ERNDIM Proficiency Scheme: Errors

## Incorrect confirmatory test

e.g. Non-ketotic hyperglycinaemia

### **Patient:**

The patient was diagnosed with non-ketotic hyperglycinaemia (OMIM 605899) due to high CSF and plasma Glycine, subsequently confirmed by enzyme assay

**Analytical performance:** All but one lab found greatly elevated glycine. Overall analytical performance was 95 %.

**Interpretative proficiency:** a diagnosis of non-ketotic hyperglycinaemia (glycine encephalopathy) was considered correct. Overall performance in interpretation was 85 %.

**Recommendations:** Analysis of glycine in **both** plasma and CSF was considered essential and glycine cleavage enzyme (EC 2.1.2.10) and mutation analysis (*GLDC*, 238300) as helpful.

	<b>n</b>	<b>points</b>
<b>Plasma and CSF glycine</b>	<b>15</b>	<b>1</b>
<b>Plasma glycine</b>	<b>2</b>	<b>0</b>
